

Theory

Overview of Client-Server Architecture:

Client-server architecture is a system where the client (user device) sends a request to the server, and the server processes the request and sends back a response.

Difference between Client-side and Server-side Processing:

Client-side Processing:

- Takes place on the user's device (browser).
- Uses HTML, CSS, JavaScript.
- Handles user interface and basic validation.

Server-side Processing:

- Takes place on the server.
- Uses languages like PHP, Python, Java, Node.js.
- Handles data processing, database operations, and authentication.

Roles:

Client:

- Sends requests.
- Displays the response.

Server:

- Receives and processes requests.
- Sends responses back to the client.

Communication Protocols:

- Rules for communication between client and server.
- Example: HTTP, HTTPS.
